## INTRODUCTION

Measurements of ozone concentration in the cabins of airline operated Boeing 747SP and 747-100 airliners are tabulated and plotted along with simultaneous measurements of atmospheric ozone concentrations existing outside the aircraft. High concentrations of ozone in the cabins of some jet aircraft are of concern to both flight crews and passengers as well as industry and government organizations. Certain physical discomfort experienced on some flights has been attributed to high levels of ambient ozone entering the cabin from the outside (refs. 1 and 2).

The simultaneous measurements of inside and outside ozone levels are necessary to determine the destruction of ozone in the aircraft pressurization - ventilation systems. This information is useful in the design of cabin ozone removal devices and systems. The relation between in the cabin and outside ozone levels is also required to determine the statistical probabilities of encountering high ozone levels in the cabin from available climatological data on atmospheric ozone.

The tabulated and plotted ozone data contained in this report permit an evaluation of the cabin ozone problem in terms of the ozone levels in the cabin of these type aircraft experienced during routine operations on certain flight routes. These data also contribute to the statistical data base of atmospheric ozone levels during several months in the peak ozone season.

Ozone measurements were taken by an airborne atmospheric sampling system as part of the NASA Global Atmospheric Sampling Program (GASP). The NASA instrumentation was installed on the Boeing 747 airliners to measure constituents of the upper atmosphere, including ozone (ref. 3). Equipment installation, maintenance, and service of the GASP instrumentation has been carried out by the United Airlines Engineering Group under contract to NASA.

Selected aircraft cabin and ambient (atmospheric) ozone measurements for two GASP equipped 747 airliners have been reported by NASA (refs. 4-8). The GASP equipped 747-100 airliner (N4711U) operated by United

Airlines obtained ozone data over the contiguous United States and to Hawaii. The 747SP aircraft (N533PA) of Pan American World Airways acquired data on many international routes.

This report presents all the cabin ozone data collected from March through December 1977. Data that has been collected after this period will be published in this same format as it is processed.

## INSTRUMENTATION

### Description of Ozone Measurement System

Instrument Type - Ozone was measured on both aircraft by commercially available ultraviolet absorption photometers modified and repackaged to operate in the airborne environment. Readings are continuous, updating every 20 seconds. Range is from 3 to 20,000 ppbv (parts per billion by volume). Operational procedures were set up to insure the integrity of the data. These include in-flight instrument health checks, instrument calibration techniques, measurement of ozone loss in the GASP air sample inlet line and pressurization system, and periodic instrument maintenance.

Modifications to the commercial-type instrument for use in the fully automated GASP system included (1) manual control mode switch replaced with logic circuits activated by the preprogrammed GASP onboard computer, (2) visual display replaced with an output shift register for digital recording of the airborne data, (3) circuits added to provide instrument identifications, and (4) output logic modified to read out a negative zero offset not available in the original instrument.

In-flight Checks and Calibration - In-flight instrument health checks, recorded with the data, monitor the instrument zero, span, and frequencies of the two electronic counters used to measure the ozone concentration. These checks are performed once each hour. Zero gas is provided for the instrument zero by directing the air sample at the proper time through an ozone scrubber in the inlet line.

All flight instruments are calibrated before installation in the aircraft and periodically thereafter using a secondary transfer standard. This standard is a laboratory-type ultraviolet photometer which was initially calibrated using a one percent neutral buffered potassium iodide (KI) method. Later in the GASP program, the standard was calibrated at the Jet Propulsion Laboratory (JPL). This calibration is traceable to the JPL five meter UV photometer described in reference 9. The KI calibration was found to be 9 percent higher than the UV photometer calibration. Thus, all published GASP ozone data are 9 percent high compared to the JPL calibrations. This is a systematic difference and can be easily corrected if the KI method is determined incorrect and other methods such as the UV photometer is adopted as the standard.

The reliability of the instruments was determined from flight and ground checks and the laboratory recalibrations following installation in the aircraft. Most component failures could be detected from the instrument output or ground checks. One type of failure (deterioration of the ozone scrubber) was detected only at the time of recalibration. Excluding failures, the stability of the ten flight instruments during one year of operation (seven calibrations per instrument) was within one percent.

A concern in the ozone measurement is the destruction of ozone in the lines from the stainless steel inlet probe to the instrument, and in the sample pump that raises the sample pressure to 1 atm. The lines are Teflon, and the pump is a Teflon coated diaphragm pump. Ozone destruction through the aircraft installed system is measured under conditions simulating operation in flight. An ozone destruct test package was developed by NASA to periodically determine this loss on the aircraft. Initial test data from different systems indicated ozone destruction from 13 to 19 percent. This was later reduced to less than 6 percent with a random error of  $\pm 2$  percent using improved materials in the pump. Thus, the random error of the total ozone measuring system was found to be less than 4 percent of reading or 3 ppbv, whichever is greater.

It has been observed that smoke injected into the instrument produces transitory fluctuations in the

readings, either positive or negative. This effect may account for some of the spikes that appear occasionally in the ozone data recorded in the cabin.

A complete description of the ozone measurement system is given in reference 10.

Equipment Installation - Ozone was measured on the two 747 airliners by equipment installed for the NASA Global Atmospheric Sampling Program (GASP) (ref. 3). The air sampling system is completely automated. Unattended operation provides continuous data acquisition during normal passenger service along established airline routes. A second ozone instrument was added to the GASP system to measure ozone in the cabin simultaneously with the outside ozone measurement.

Location of sample air inlets - The points where ozone was measured outside and inside the 747 cabin are shown figures 1 and 2. Air from outside the aircraft was sampled by a special external probe extending beyond the boundary layer near the nose of the aircraft. Air flowed in a 2.54 cm. diameter tube from the probe to the ozone instrument and associated equipment mounted on a special rack below the passenger deck at about station 360. Air from inside the aircraft was sampled at only one point in the cabin. Air was drawn from a 0.62 cm. diameter port about 1.5 m. above the floor in the right outside wall of the staircase to the upper deck (left side of the right isle). A Teflon ring attached to the wall extended the inlet to the port about 0.62 cm. from the wall surface (detail in fig. 2). This minimized drawing air from along the wall surface into the sample since ozone can be destroyed by contact with surfaces. About 6 m. of 0.62 cm. diameter Teflon-coated tubing was used between this port and the ozone analyzer on the GASP rack. The tubing was cleaned and found to cause negligible loss of ozone.

Air sample pressurization - Although unpressurized air is desirable to avoid altering the air constituent being measured, measurements such as ozone need a pressurized air sample to achieve the desired instrument sensitivity. A diaphragm or bellows-type pump was used to increase the low pressure air at altitude to one atmosphere pressure. A pressure regulation

system holds the inlet pressure to the instruments constant at  $1 \pm 0.007$  atm. at altitudes up to 13.78 km with a flow rate of 14 liters/min.

Data Acquisition System - Ozone data (atmospheric and in-cabin) are taken with the existing GASP data acquisition and control system. All major components of this system are airborne units used by many airlines in normal flight data recording systems. The preprogrammed processor for automatic system control is a modified Data Management Unit. This unit also provides certain data acquisition functions. Additional data acquisition is handled by a standard flight data acquisition unit. All data are recorded on a digital cassette recorder which is the same type Digital Aids Recorder (DAR) used by airlines for flight recording. The GASP system is autonomous having dedicated units for all data acquisition and system control.

Instruments are turned on during aircraft pre-flight. The computer or processor takes over control just prior to takeoff. A standby condition is held until a signal is received by the processor from the altimeter to set up the system for sampling. This was set at 6.1 km (20,000 ft.). A basic 60-minute sampling cycle is constructed by alternating 5-minute air sampling and 5-minute calibration modes. Thus, there are six sample readings and six different calibrations taken each cycle. All data are recorded during a 16-second period at the end of each 5-minute air sampling and calibration mode. The ozone instrument requires only four calibrations during each 1 hour cycle. Thus, ozone measurements are taken every 10 minutes during the first 40 minutes of the cycle and every 5 minutes during the remaining 20 minutes. Before landing, the system is returned to a standby condition. The time, position of the aircraft, altitude, speed and direction are recorded and thus pinpoint each ozone measurement.

Data Reduction Procedure - The tape recorder cassettes are removed from the aircraft about every two weeks. In-flight data on the cassettes are transcribed onto computer compatible tape which is shipped to NASA Lewis Research Center. This tape is initially processed at NASA to provide a direct printout of the flight data, dividing the continuous data record into flight

segments based on flight origin and destination. Further data processing includes the ozone system calibration correction, deletion of questionable and redundant data, and a re-transcription to a final format (refs. 6 and 7).

#### PRESENTATION OF DATA

All GASP data, including the cabin and ambient ozone data presented herein, are available to the public on magnetic computer tape from the National Climatic Center, Federal Building, Asheville, NC 28801. In addition to providing compact storage of a large amount of data, the availability of the data on computer tape facilitates data analysis and alternate presentations which would be awkward if not impossible from the hard copy.

The data tabulated and plotted here are from GASP Tapes VL0009, VL0010, VL0012 and VL0014. These tapes include all data obtained by GASP equipped aircraft N533PA and N4711U from January 3, 1977 through January 3, 1978. Flight routes and dates, instrumentation, data processing procedures, data tape specifications, and selected analysis of the cabin ozone data are reported in refs. 6 and 7.

#### Explanation of Data Tables and Plots

Tabulation and plots of all data - The plots and tables of GASP ozone data are organized chronologically by aircraft in appendixes A and B for the 747SP (N533PA) and 747-100 (N4711U) aircraft respectively. In the plots for each flight, the upper panel gives the altitude (boxes) and latitude (crosses), the center panel gives the ambient (boxes) and cabin (crosses) ozone levels, and the lower panel gives the ratio (cabin divided by ambient). The altitude, ambient ozone, and ratio data are jointed by solid lines and latitude and cabin ozone are joined by segmented lines whenever the time between observations is 10 minutes or less (data are plotted at the multiple of 5 minutes nearest to their actual elapsed time). Data points are not connected if the time interval is greater than ten minutes. For ambient ozone less than 0.1 ppmv, the corresponding ratios are not plotted or tabulated. Each table has a heading where the departure and arrival airports are identified by the standard

three-letter airport code (ref. 11), and the departure date and the aircraft number are given. The remainder of the heading is self-explanatory, although special cases arise: if no ambient ozone values were observed on a flight, then stars are entered for the maximum ambient ozone value and the maximum ratio value is given as zero; if no ambient ozone value greater than 0.1 ppmv was observed, then stars are entered for the maximum ratio value.

In the tables, ETIM is the elapsed time after the time of the first data record on the flight. RATIO is the cabin ozone amount divided by the ambient ozone amount. If any variable in the tables is missing, its position in the table is left blank. Observations are entered at minimum time intervals of 5 minutes (during the data processing, any observations made less than 5 minutes after the most recent acceptable observation were disregarded). If two or more observations were made during the same GMT minute, they were averaged together and an "A" is entered after the GMT. If the GMT was missing for an observation, then for all following observations on the flight, the elapsed time between observations was computed using the aircraft speed and the distance travelled between the geographic coordinates of the data points. The GMT of each observation was then estimated by adding the computed elapsed time to the GMT of the previous observation. In these cases an "M" is entered in the table after the GMT, unless two or more observations had the same estimated GMT in which case the "A" tag takes precedence.

During the period April 2 through August 6, 1977, 15th stage compressor bleed was used intermittently on N533PA to reduce cabin ozone levels (refs. 4, 5, and 7). The high temperature (340°C - 480°C) associated with this stage dissociates much of the ambient ozone that would be otherwise coming into the cabin using the normal lower temperature compressor bleed. After May 15 the use of 15th stage bleed was coded into the onboard GASP data recording. Whenever the data records indicate bleed was in use a "B" is entered in the tables after the ratio value.

Summary tabulations - A data summary, by flight, for all GASP flights with cabin and/or ambient ozone from January - December, 1977 is given in appendixes C

and D, for aircraft N533PA and N4711U respectively. The parameters presented were selected based on the requirements of reference 2 and include, for each flight, the departure date, route, mean flight level, data time interval, and cabin and ambient ozone data. All ozone levels are expressed as parts per million by volume (ppmv).

Entries appear for all flights from tapes VL0009 (ref. 6), VL0010 and VL0012 (ref. 7), and VL0014 for which cabin and/or ambient ozone data are available. The number of cabin ozone measurements for each flight is given in the column headed ND following the departure date, route, and mean flight level. The elapsed time from the first to the last cabin ozone measurement for each flight is given in the TOTAL time column. An 'M' next to the TOTAL indicates that the observation time was not available for one or more cabin ozone measurements during the flight. Note that since the GASP system does not obtain data at altitudes below FL 195, the TOTAL time here is less than the segment time specified in reference 2. The time during which the cabin ozone level exceeded 0.1 ppmv is given in the 03 > .1 column; and the time during which the cabin ozone level exceeded 0.3 ppmv is given in the 03 > .3 column.

The mean (MEAN) and mean plus 1 standard deviation ( $M + SD$ ) cabin ozone levels are time-weighted averages over the time period given by TOTAL. The maximum observed cabin ozone levels are also listed. The maximum time-weighted average cabin ozone level during any two hour interval in the flight is given under 2HR. If TOTAL is less than 2 hours, the value appearing in the 2HR column is the flight mean.

Next, the number of data points, time-weighted mean and mean plus 1 standard deviation, and maximum values of ambient ozone data are given for each flight. For measurement periods in which both cabin and ambient ozone data are available, and in which the ambient ozone level is greater than 0.1 ppmv, the ratio of cabin to ambient ozone is calculated. The number of these data points, as well as the mean and standard deviation are given following the ambient ozone data for each flight.

The final column in the Summary Tabulations indicates the compressor bleed/filter status, when available, for aircraft N533PA. The tags in this column identify operational and configuration changes made by the airline in efforts to reduce cabin ozone levels. A "B" in this column for flights after May 12, 1977 indicates that high temperature (15th compressor stage) bleed was used for cabin air during one or more measurement periods in the flight. Because independent documentation on the use of 15th stage bleed is not available for flights prior to May 12th, these are identified by a '?', although 15th stage bleed was used prior to this date. Flights and time intervals in which high temperature bleed was used are generally readily apparent in the flight plots, as shown by a marked decrease in the ratio of cabin to ambient ozone. An 'F' in the final column identifies flights after a charcoal filter system was installed on August 6, 1977. Note that this column applies only to aircraft N533PA (appendix C). There were no air conditioning system modifications or use of high temperature bleed for cabin air on N4711U (appendix D). Further analysis of these data are given in refs. 6 and 7.

Table I summarizes the simultaneous cabin and ambient ozone data for both GASP equipped aircraft. As our purpose here is to consider only those times when ozone may be a problem, only those cases when the ambient ozone amount was above 0.1 ppmv are included in the table. Thus, the statistics in table I generally refer to stratospheric flights. There may be factors other than those listed which influence the retention ratio from flight to flight, or even within a flight, such as load factor or flight duration (ref. 5). A measure of the variability of the retention ratio is given by its standard deviation, which has been included in table I.

#### SUMMARY OF RESULTS

Measurements of ozone concentrations both outside and in the cabin of an airline operated Boeing 747SP and Boeing 747-100 airliner are tabulated and plotted. Tables and the corresponding plots for each flight are arranged chronologically for the two aircraft. Data were taken at five or ten minute intervals by automated

instrumentation used in the NASA Global Atmospheric Sampling Program (GASP). All cabin ozone data obtained by GASP-equipped airliners N533PA and N4711U during 1977 are presented.

HND TO JFK (PAGE 1 OF 1)

DEPARTURE: 10 JUL 77

AIRCRAFT: PANAM -N533PA

MAXIMUM VALUES: AMBIENT OZONE=.593 CABIN OZONE=.293 RATIO (LIMITED TO AMB. OZONE ABOVE 0.1)=1.02 TOTAL OBS IN CABIN: 84  
DATA SOURCE: GASP TAPE VL010, FILE 4 AN "A" AFTER THE GMT BELOW DENOTES MORE THAN ONE OBSERVATION WAS AVERAGED

A-554

LAX TO AKL (PAGE 1 OF 2)

DEPARTURE: 25 DEC 77

AIRCRAFT: PANAM -N533PA

MAXIMUM VALUES: AMBIENT OZONE=\*\*\*\* CABIN OZONE=.022 RATIO (LIMITED TO AMB. OZONE ABOVE 0.1)= .00 TOTAL OBS IN CABIN: 93  
DATA SOURCE: GASP TAPE VL014, FILE 1 AN "A" AFTER THE GMT BELOW DENOTES MORE THAN ONE OBSERVATION WAS AVERAGED
